Perceptual identification in priming studies

- Short-term priming: a “prime” word followed by a “target” word.

- In a 2AFC lexical decision, nurse is recognized as a word more easily (Meyer & Schvaneveldt, 1971).

Questions

- In perceiving sequences, how does previous items affect later items?

Overview

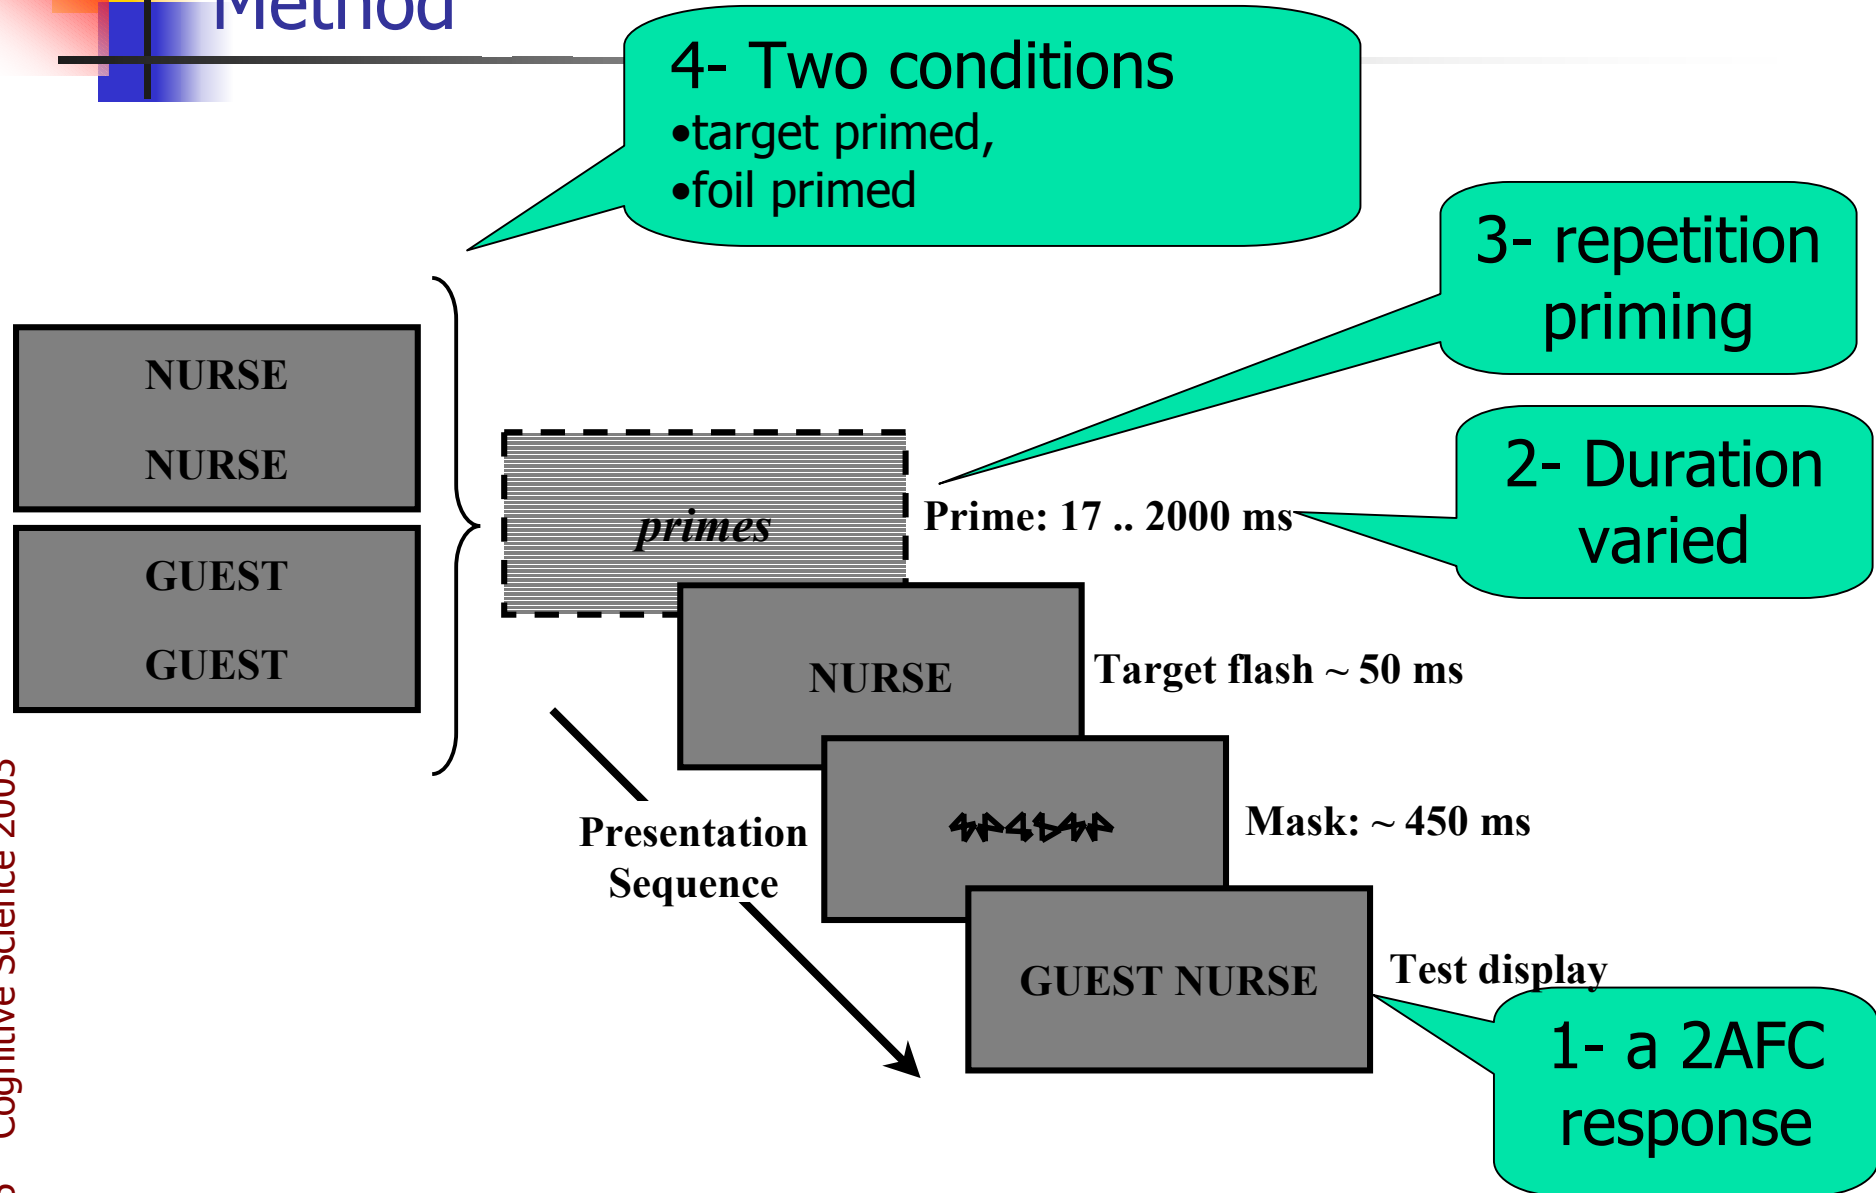

- Phenomenon:
 - Choice data:
 - Choice preferences.
 - Is it discounting –or– saturation?
 - Response times (RT):
 - What is the time course of a correct response?
 - Modeling:
 - A race model of RT decisions and of percent correct
- A- Experiment 1
 - Choice preferences
 - Response times
 - B- Race model of RTs
 - C- One test of the model

A- Experiment 1

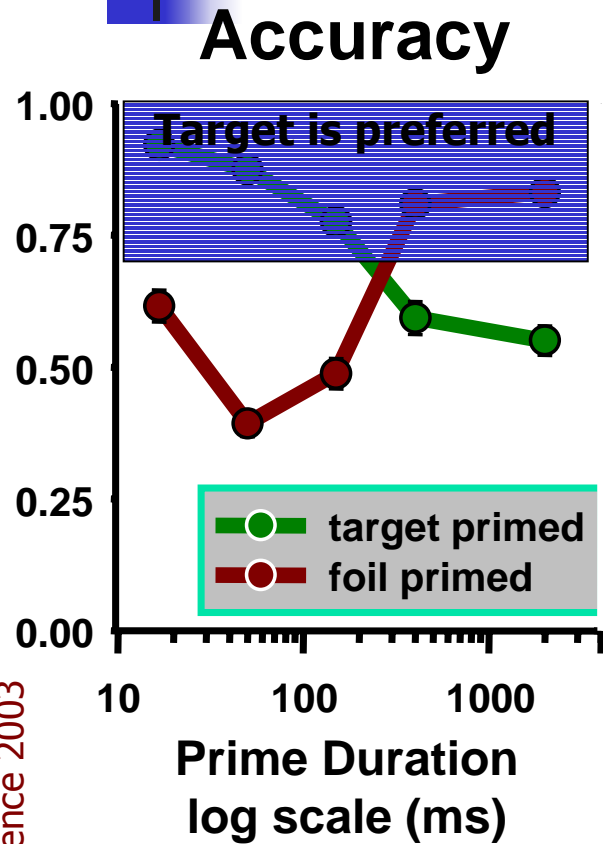

A- Experiment 1

Method

A- Experiment 1

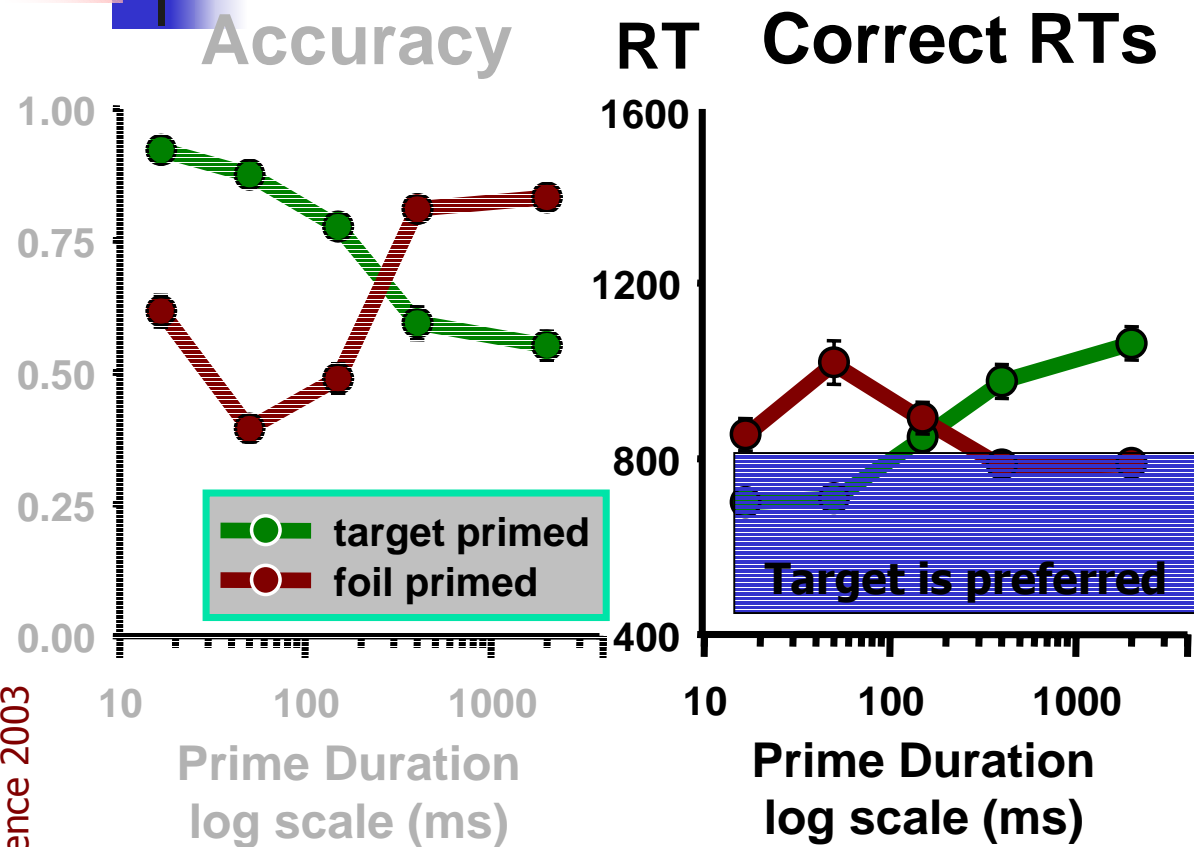

Results a) accuracy

- Short prime durations (below 300 ms):
 - A preference to choose the repeated word
- Long prime durations (above 300 ms):
 - The preference reversed (the primed alternative is "mistrusted").

A- Experiment 1

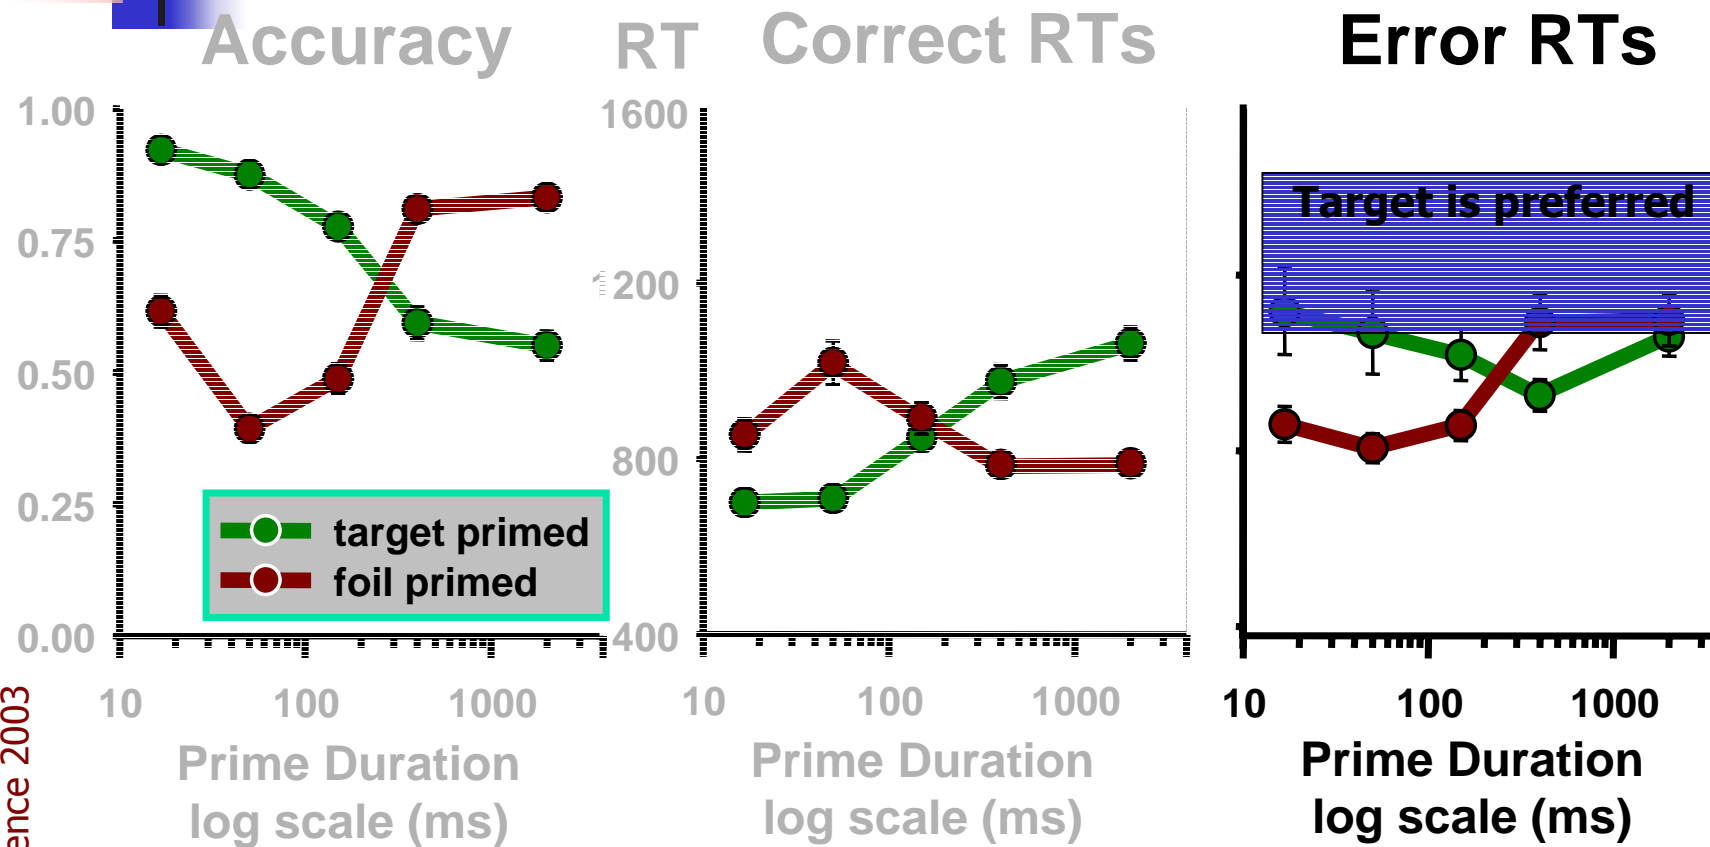

Results b) Response times for correct responses

- The target is chosen rapidly when it is the preferred alternative;
 - The target is chosen slowly when the foil is the preferred alternative.
- Faster → more accurate

A- Experiment 1

Results c) Response times for error responses

- The foil is chosen rapidly when it is preferred;
- The foil is chosen slowly when the target is preferred.
Faster → less accurate

A- Experiment 1

Conclusion

- Choice:
 - Preference for repeated word if primed briefly. As if:
 - The participants are aware of a possible source confusion and tries to discount it (Baysian approach, ROUSE, Huber et al., 2000; inhibition and neural networks approach, nROUSE, Huber et al., 2002) –or –
 - The system is saturated and cannot devote as many processors to the primed word after a certain time.

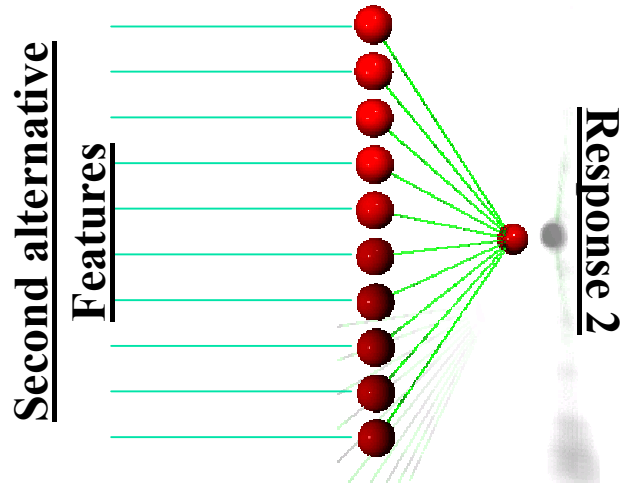

- RTs:
 - The preferred word is chosen rapidly. As if:
 - The alternative were racing but the preferred alternative started ahead of time.

B- Race model of RTs

B- Race model of RTs

ROUSE and race model

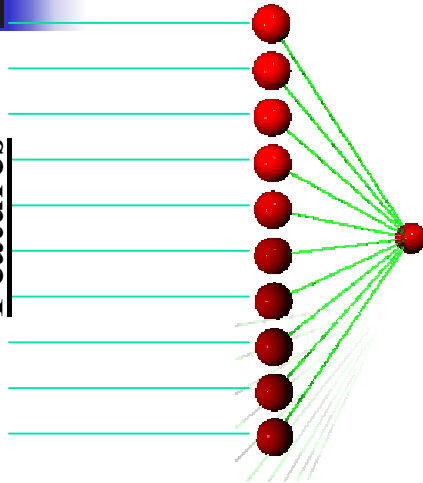

- The units on the first layers take their activation from the stimuli
- The units on the second layer accumulate evidences for either alternatives.
- The first output unit that fires triggers a response
 - Race model

B- Race model of RTs

Computations

First alternative

Features

$$f_1(t) = \Pr(\mathbf{T}_1 < t)$$

Assuming that the target is the first alternative:

$$\begin{aligned} f_c(t) &= \Pr(\mathbf{T}_1 = t \ \& \ \mathbf{T}_2 > t) \\ &= \Pr(\mathbf{T}_1 = t) \Pr(\mathbf{T}_2 > t) \\ &= \Pr(\mathbf{T}_1 = t) \Pr(\mathbf{T}_2 > t) \\ &= f_1(t)(1 - F_2(t)) \end{aligned}$$

$$\begin{aligned} P(c) &= \int_{\forall x} f_c(t) dt \\ &= \int_{\forall t} f_1(t)(1 - F_2(t)) dt \end{aligned}$$

analytic →

← **best-fit**

$$f_c(t) = \Pr(\mathbf{T}_1 < \mathbf{T}_2)$$

$$P(c) = 75\%$$

$$\text{Mean}(c) = 43$$

$$\text{Mean}(e) = 51$$

$$f_E(t) = \Pr(\mathbf{T}_2 < \mathbf{T}_1)$$

Second alternative

Features

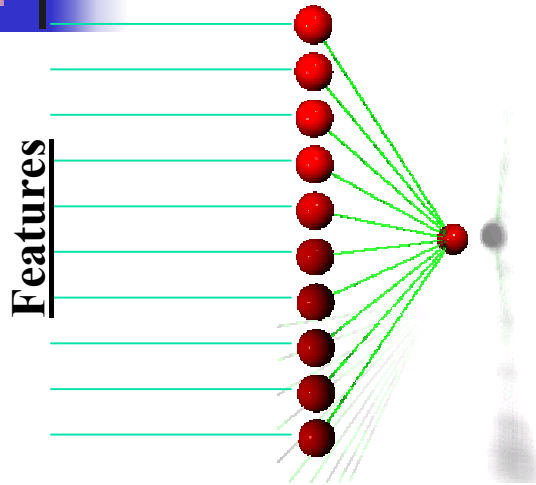

$$f_2(t) = \Pr(\mathbf{T}_2 < t)$$

B- Race model of RTs

Asymptotic statistics of extremes

First alternative

Second alternative

- What are the f distributions?
 - According to the Extreme Limit Theorem (Cousineau et al, JMP 2002),
 - and assuming there are many features in competition to fill each response unit,
 - the output of one unit should be a Weibull distribution
 $f(t) = W(t | \xi, \alpha, k)$:

B- Race model of RTs

What could the prime do?

No prime condition

Both alternative have the same distribution of finishing time.

Priming alternative 1

Scenario 1

-or-

Scenario 2

The onset –or– the scale parameter can be reduced.

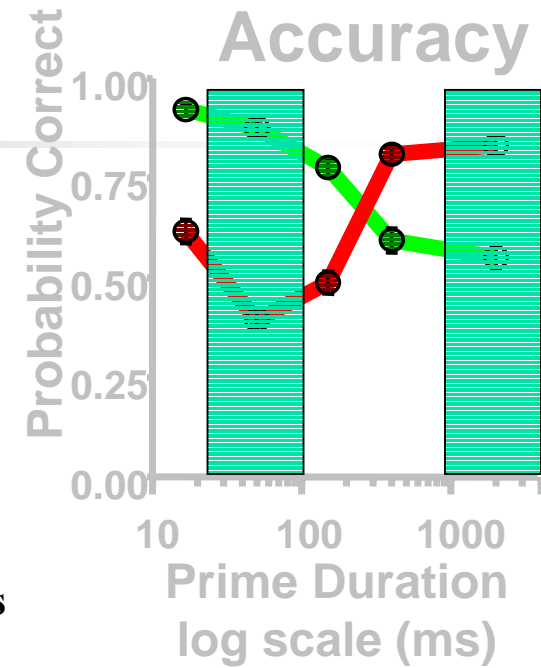

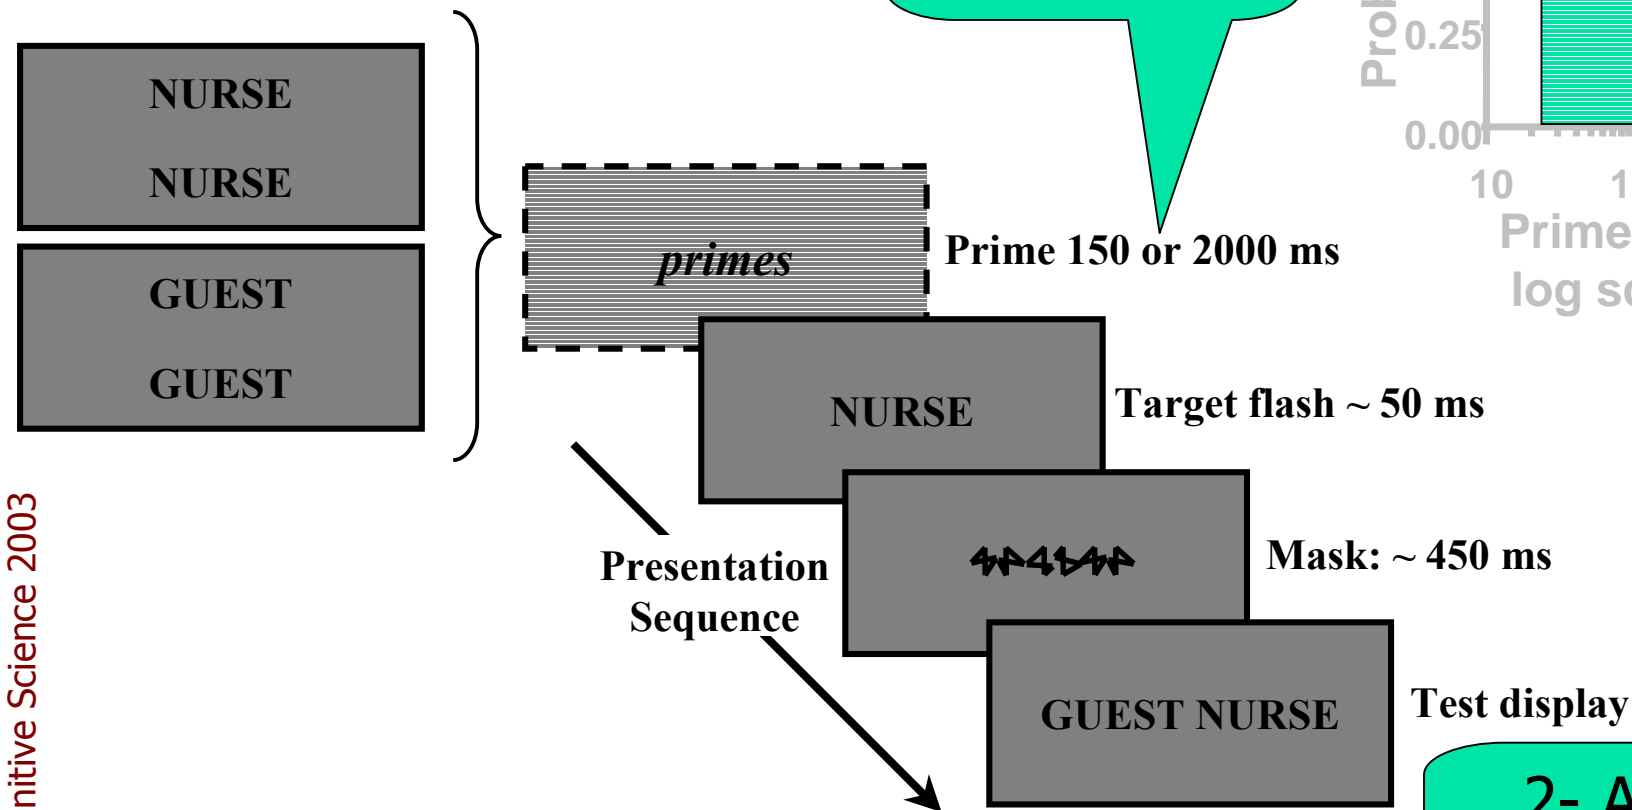

The shape parameter was kept a constant for all subjects in all conditions ($k = 1.3$).

C- Experiment 2

C- Experiment 2

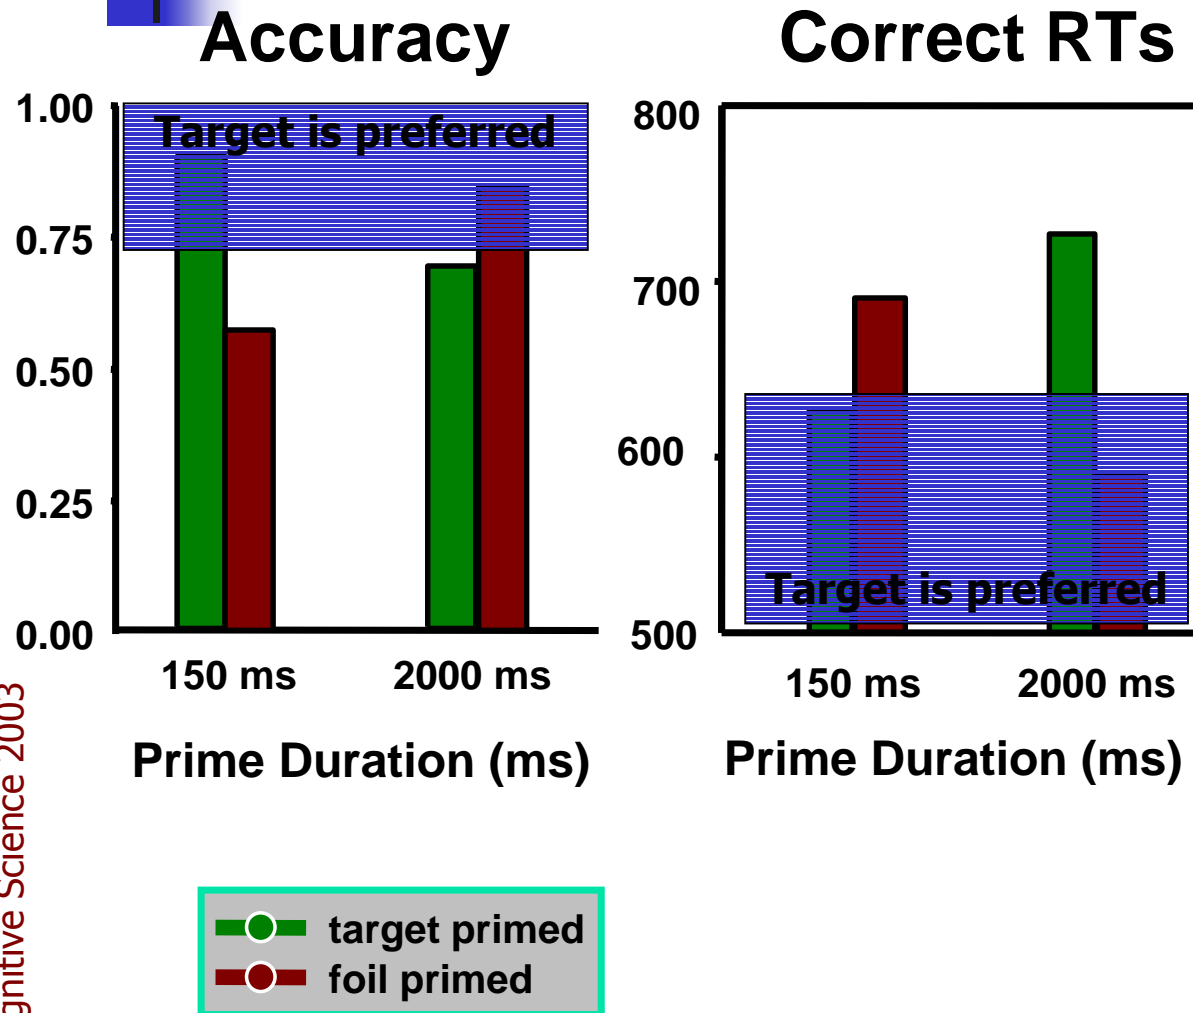

Method

2- A lot of trials.

C- Experiment 2

Results a) Response times for correct responses

Choice:

- Same preferences, with a reversal for long prime duration.

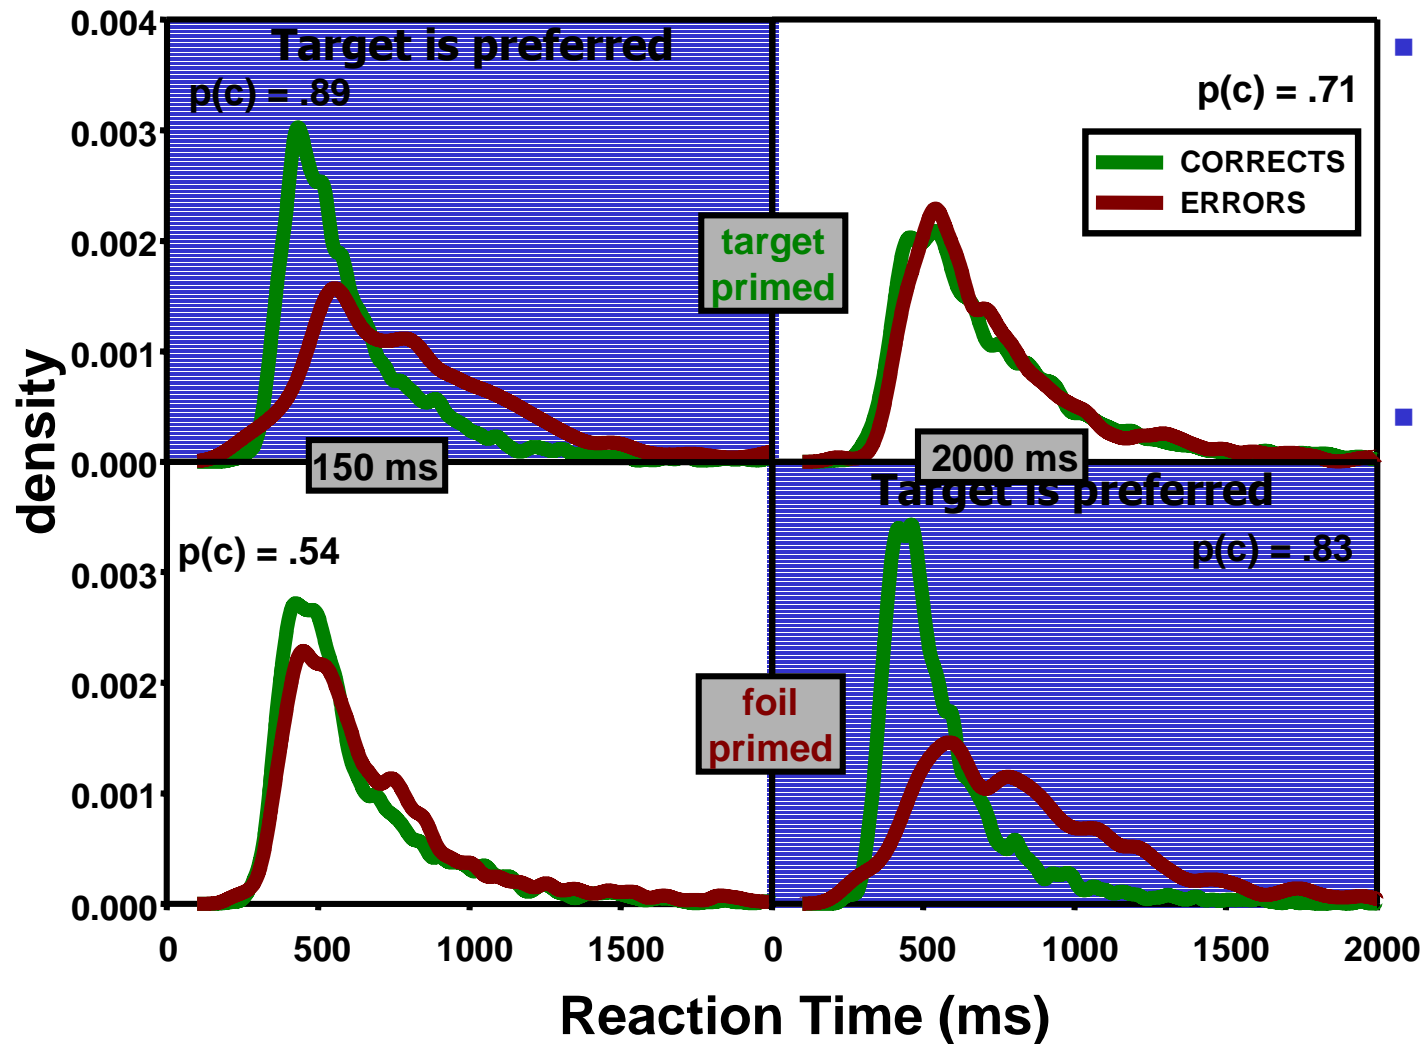

RTs:

- Preferred is faster

Replicates the previous findings.

C- Experiment 2

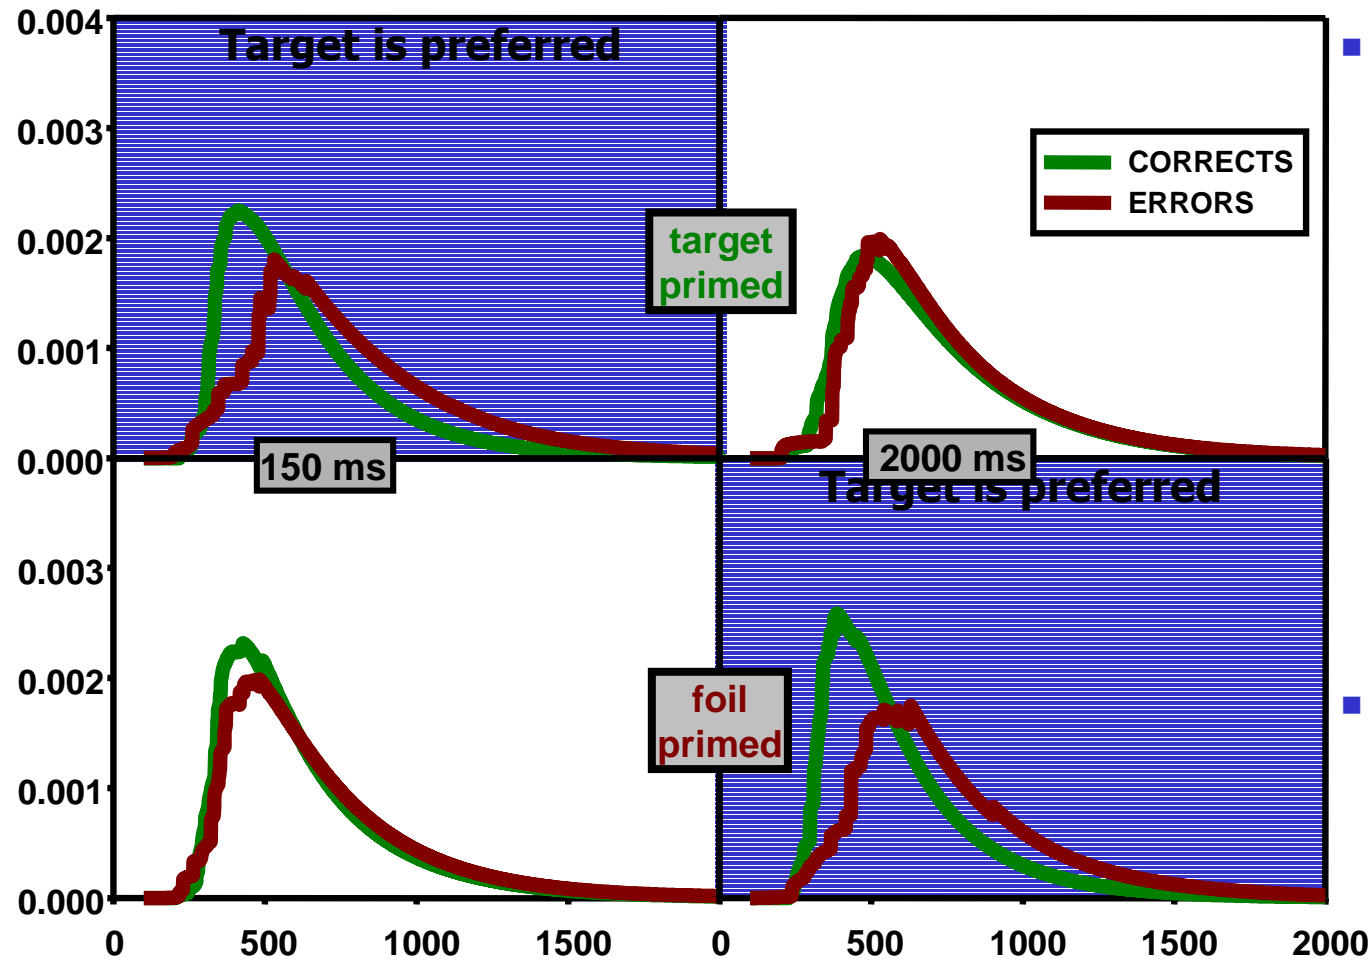

Results b) Observed distributions of RT

- The most accurate responses also have the smallest overlap.
- When the target is preferred, the scale is much smaller (favoring scenario 2).

C- Experiment 2

Model a) Predicted distributions

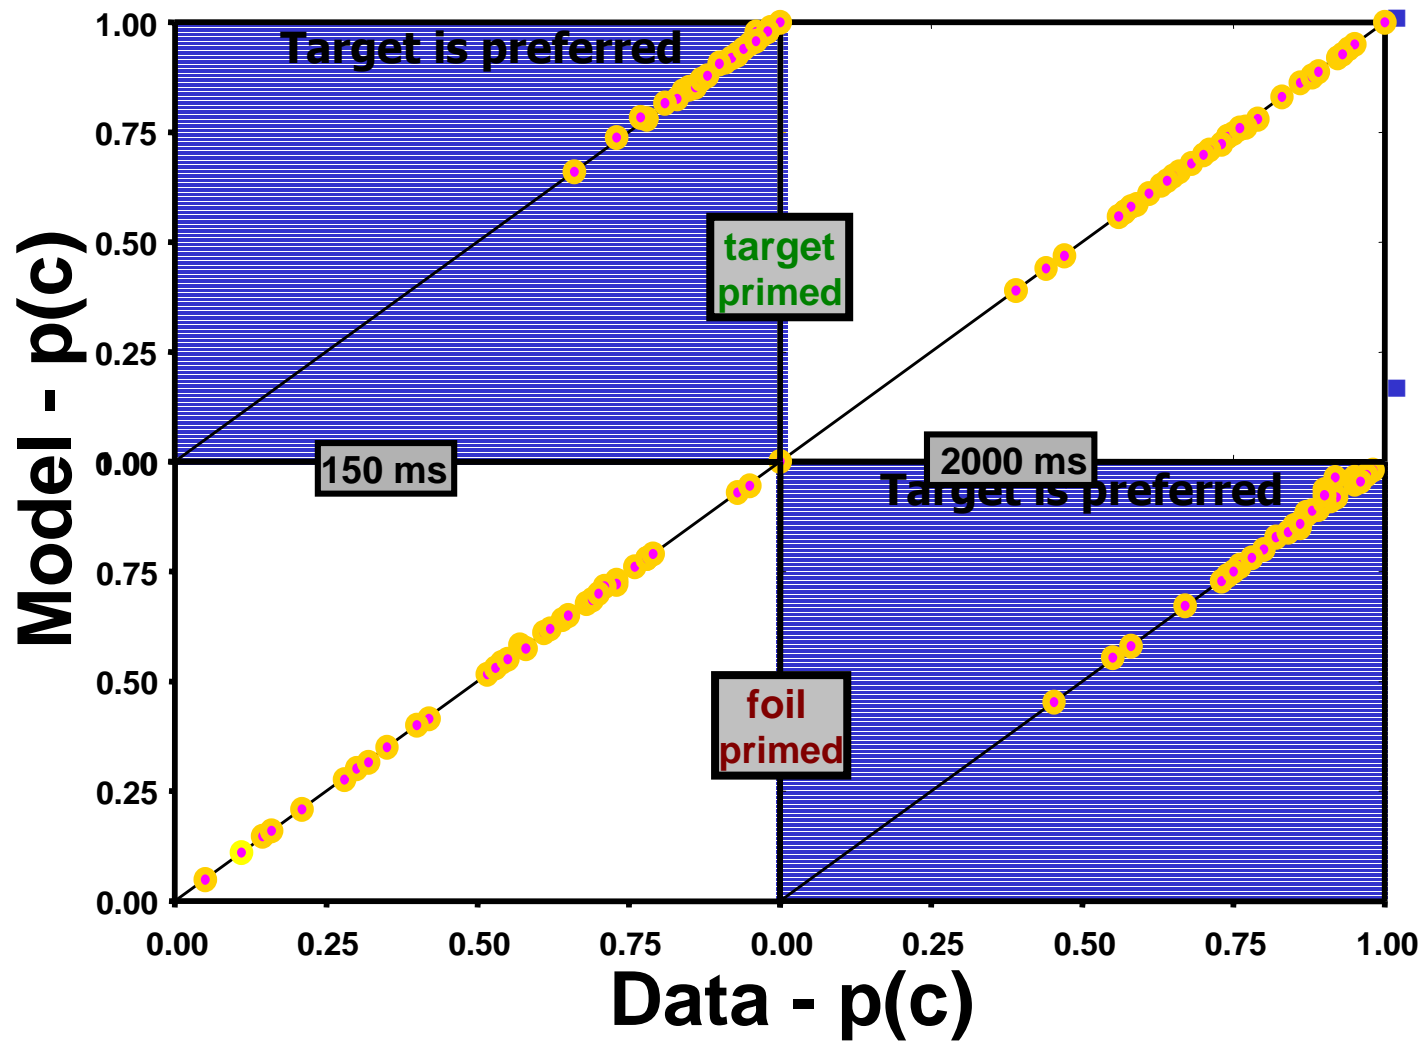

- For each subject and each cell, given f_c and f_e , we searched for the best fitting f_1 and f_2 , allowing changes in the onset (scenario 1) and the scale (scenario 2).

- Shown are f_c and f_e inferred from the model.

C- Experiment 2

Model b) Predicted error vs. observed error

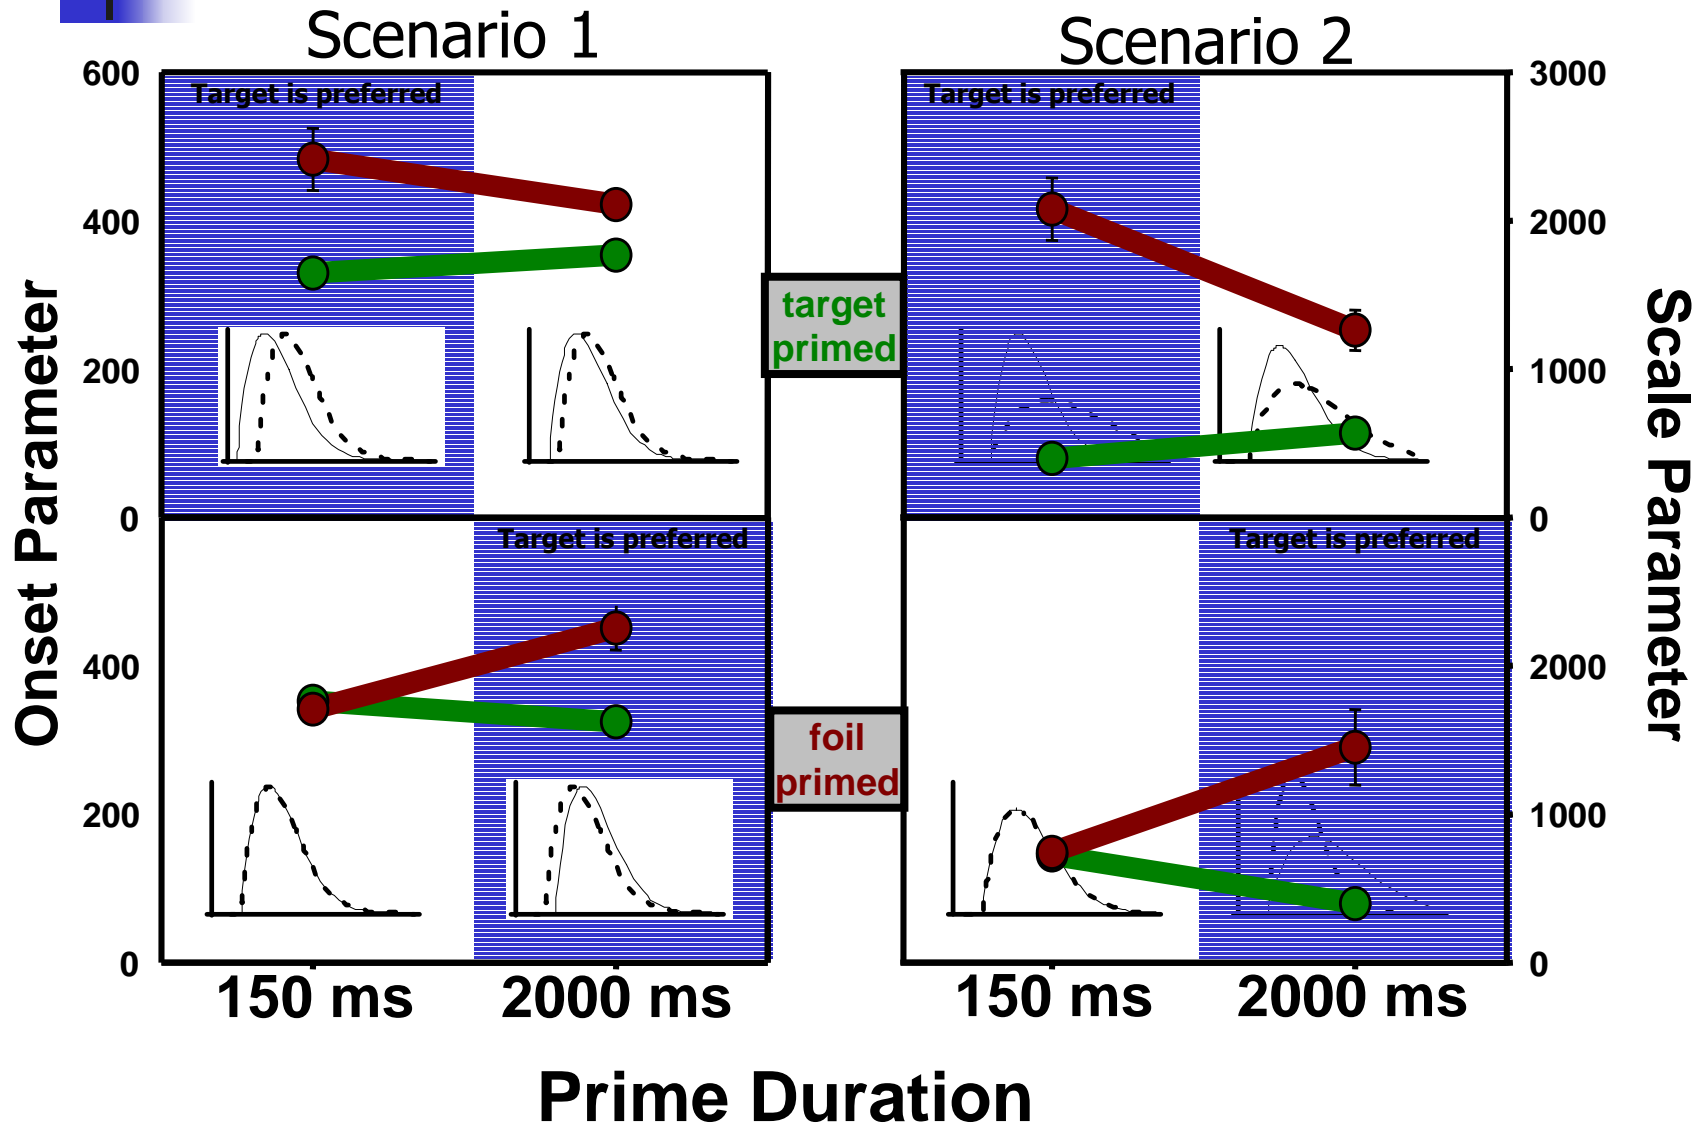

From the estimated f_1 and f_2 , the percent correct can be computed

They match the data very well.

asdf

C- Experiment 2

Model c) Estimated parameters

Conclusions

The role of synaptic fatigue

First alternative

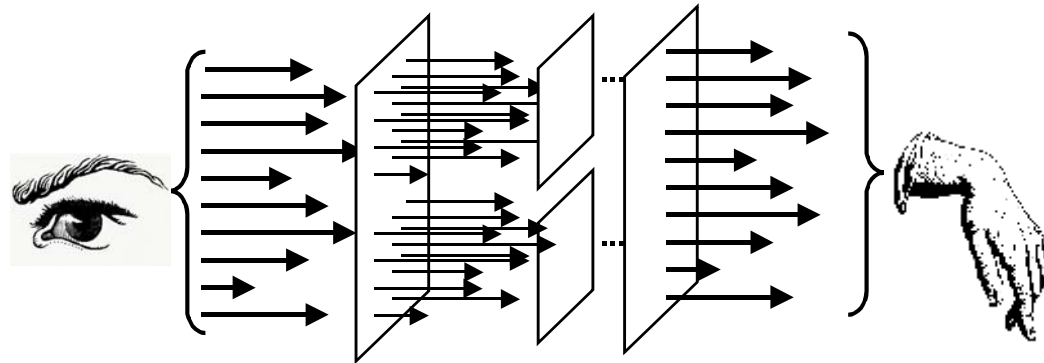

- Short activations persists in the system
 - With source confusion, it is difficult to say whether the activation comes from the prime or from the target;
- Long activations saturates the feature detectors
 - Part of the detectors being off, the other word is preferred

Second alternative

Concluding remarks

Not much occurs at the perceptual level;

Residual activation
→ "cognitive facilitation"

Facilitations create preferences (biases) that can cause erroneous responses

The ubiquitous presence of priming?

Thanks.

Appendix: Perceptual facilitation?

Perceptual facilitation?

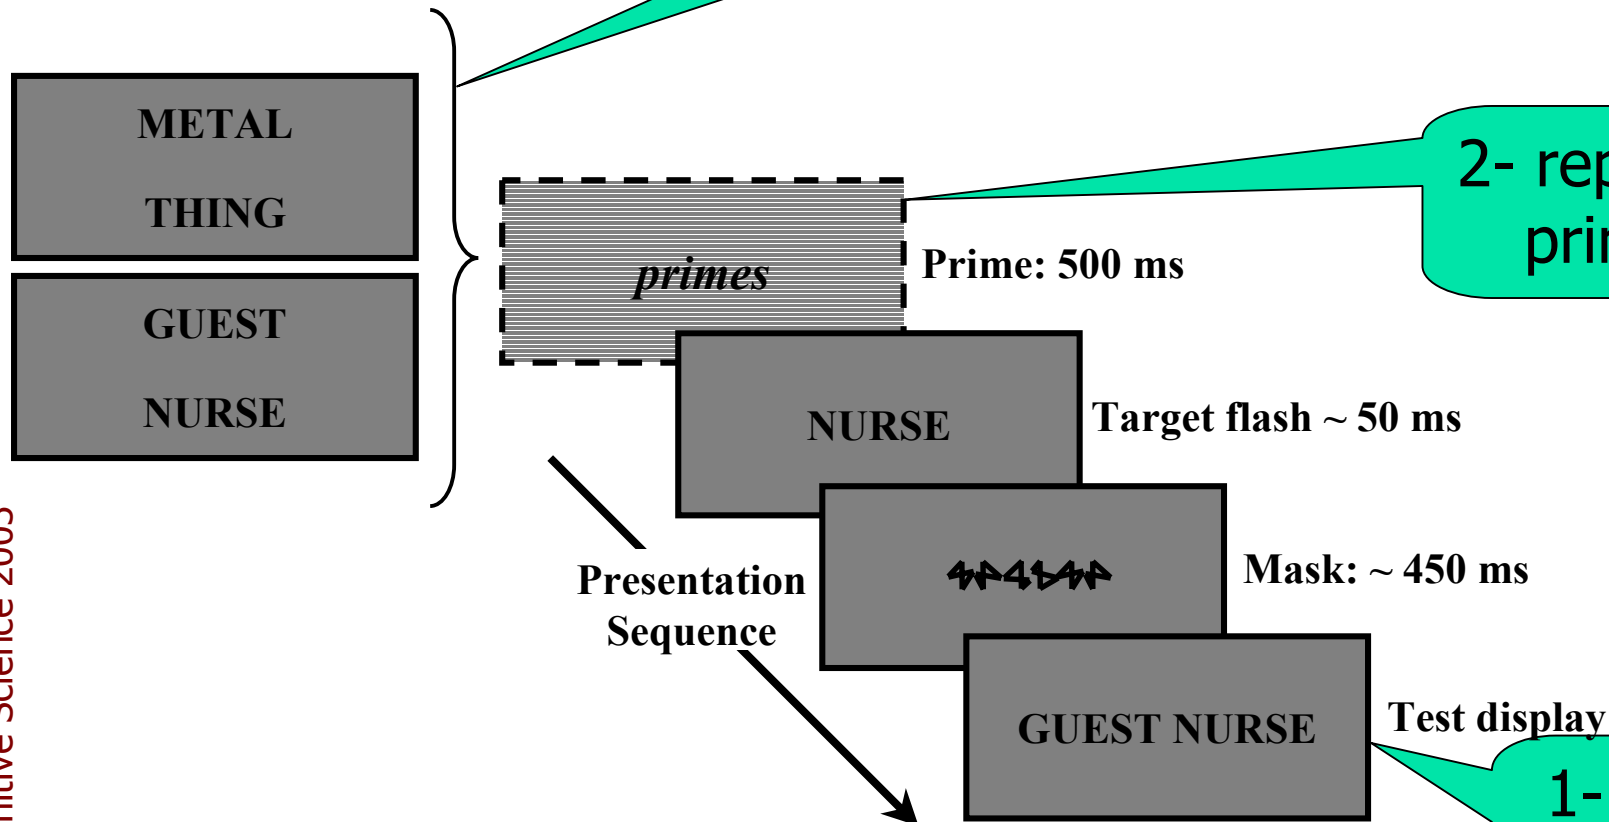

Experiment 1

3- TWO primes:

- Neither alternative,
- both alternatives.

2- repetition priming

1- a 2AFC response

Perceptual facilitation?

Results a) perceptual facilitation

- If there is perceptual facilitation when the target is presented (as in the “both primed” condition), then $P(c)$ should be larger than when it is not present.
- The reverse is observed: a “Both primed” deficit
- No evidence of perceptual facilitation.
